1 Overview

1.1 Background

The CSIR is actively developing a distributed simulation framework that ties in with various other real systems and is used to exchange information between them. The client has a number of configurations of this system depending on the requirements of the client which can involve various external applications as well.

One of the issues the client has is to quickly distribute the latest build or configuration files of their software over various computers that are needed for an experiment. In some cases the same computers may be used for other experiments which mean each of the computers may need to have various builds and configuration options.

Another issue they experience is the running, stopping and restarting of the complete simulation. During a simulation it may be determined that certain configuration options may need to be changed and distributed to the affected machines, in which case either all or some components will need to be restarted which can become tedious and time consuming.

1.2 Business opportunity

The goal of our project is to develop an application which is able to maintain various build versions of the simulation framework and distribute these builds to certain designated machines that may be required for an experiment. The application will monitor system statistics of the various machines attached to an experiment and will have the ability to execute applications on those machines which will have different configuration options.

The application will consist of a master and slave component where the master is used to control the distribution of slaves. From the master one will be able to start an experiment which will run the relevant applications on all the necessary machines.

2 Purpose of this document

This document is intended to assist users of the application, known as AppMan and AppManClient, with necessary tasks.

3 Server use

3.1 Start Server

The server is started automatically, but after a manual stop can be restarted manually as follows:

3.2 Stop Server

The server can be stopped using this menu item:

3.3 Set Port

The port can be changed from the default, effect will be taken when the server is restarted via a stop then start. The process looks as follows:

4 Build related

4.1 Add Build to AppMan (Master)

A build can be added on the master as follows, all the info, except build description is compulsory.

4.2 Copy Build to AppManClient (Slave)

The build can be copied in the following way:

5 Simulation related

5.1 Add Simulation

To add a simulation one must have at least one slave added. The available slaves are displayed as checkbox items. A build or application can then be selected via a drop down box. If necessary command line arguments are then

typed in. Once all the information is captured one can add the simulation. See below:

5.2 Execute Simulation

A simulation can be selected on the treewidget, then double-click the selected simulation. This will send the argument and required build or application name over the network, along with the command line arguments to the necessary slave. See below:

6 Machine related

6.1 Add Slave

On the AppManClient one sets the port and Master IP then clicks connect. These are then stored in a settings file for future use.

6.2 Request System Information

When a slave is clicked the request is automatically sent to the slave, then displayed in a docking widget as follows.

7 AppManClient

7.1 Add Build

Adding a build on the client side works as follows:

7.2 Add Application to AppList

This is done for preinstalled programs and works as follows:

7.3 View builds

When the button is clicked, all builds and applications are displayed in a new window. See below:

8 Glossary

- Build - An application build version that could potentially be distributed to slave computers.
- Slave - A computer that will be controlled via a master computer. Application builds will be sent to this computer.
- Master - A computer that will control Slaves across a network.
- Server - A machine waiting on the network for connections from other machines.
- GUI - Graphical User Interface with which a user can control the project.
- Project - This project. The distributed application manager.
- Application - A 3rd party program the client may use during simulations
